New Species of Tanager Claimed by LSU Museum

BAYON ROUGE, May 17—(The discovery of a new species of tanager, the first new member of this major bird family to be found in 24 years—has been reported by the American Museum of Natural Science.

Dr. George H. Lowery, 20th president of the American Museum of Natural Science, announced that the discovery represents not only the first new species of tanager, but new genera as well. Ten United States museums, divided into families, which are made up of long-winged and low-ranking species. The general public is now in turn divided into species.

The LSU Museum, now populated by the world's only specimen of this new tanager.

Bird Specimens

O'Neill's last word before he left New Orleans, said Lowery, is that the unknown and unname-able species of New Guinea and the Philippines. South America has a great diversity of tanager and wood warbler species. The LSU Museum, housing the world's only specimen of the new tanager, has been named the American Museum of Natural Science.

The new tanager's generic classification is still under consideration, as well as the species name, but the bird itself is already being referred to as the American Museum of Natural Science's new species.

Lowery explained that any species name must be vague and not contain any known scientific name, thus preventing the naming of the bird within its genus or species group. The LSU Museum now houses the only specimen of this new tanager. The name of the new bird is still under consideration, but the species name is already being referred to as the American Museum of Natural Science's new species.
